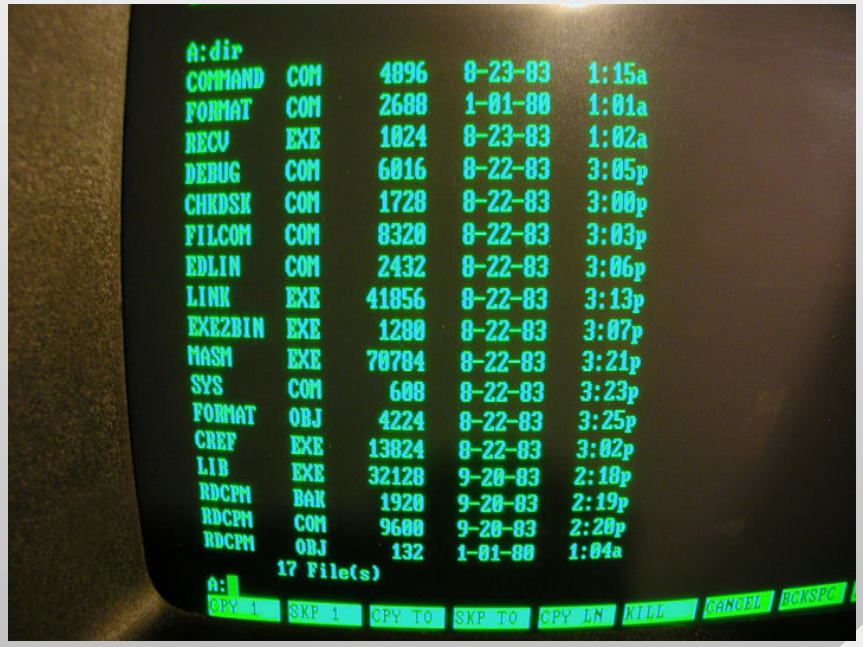
## Operating Systems

Dmitri Loguinov
Texas A&M University

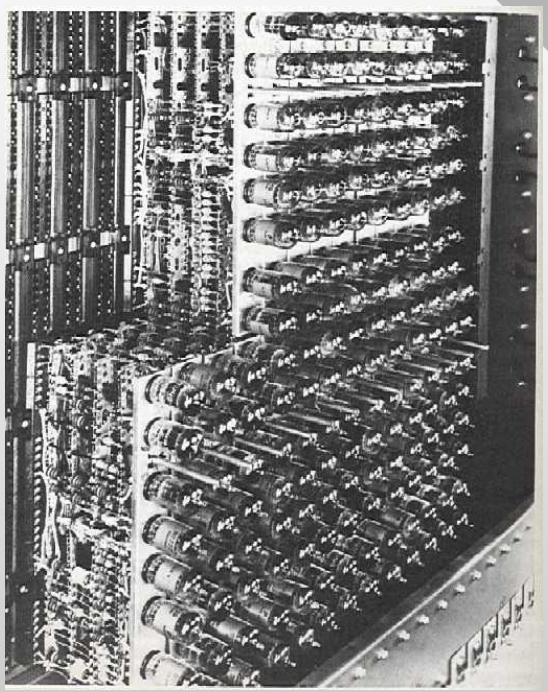
January 23, 2018

# Chapter 2: Book Overview

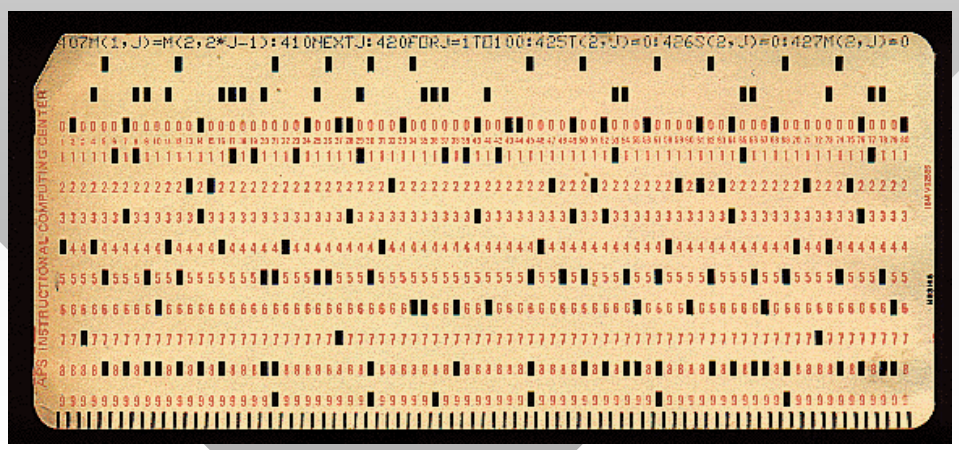
- Lectures skip chapter 1
  - Mostly 312 background with some examples
- Our goal in chapter 2
  - Understand the motivation for building an OS
  - Introduce basic terminology and history
  - Glance over the main concepts studied later



# Chapter 2: Motivation



- Early computers (1940-1950s) did not have an OS
- Programs (called jobs) were loaded manually from punch cards
  - Errors were indicated by lights
  - Printer output signaled successful completion
- Three main problems:
  - Scheduling inefficiency
  - Setup delays
  - Hardware awareness



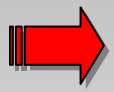
IBM punch card (invented in 1928)

# Chapter 2: Motivation

- Scheduling difficulties
  - Sign-up sheet to reserve computer time
  - Wasted resources if job finishes quicker than reserved time
  - Forced termination and repeated visits if taking too long
- Setup delays
  - Loading compiler, source code, libraries, input data, and linking involved mounting tapes and/or card decks
  - If an error occurred, the user had to restart the process
  - Considerable time dedicated to setting up the program to run
- Hardware awareness
  - Programmer had to write directly into device registers in every program, keep track of hardware changes
  - Time wasted on largely irrelevant code development

# Chapter 2: Roadmap

2.1 OS objectives and functions



2.2 Evolution of the OS

2.3 Major achievements

2.4 Other developments

2.5 Virtual Machines

2.6 Multi-core considerations

2.7 MS Windows

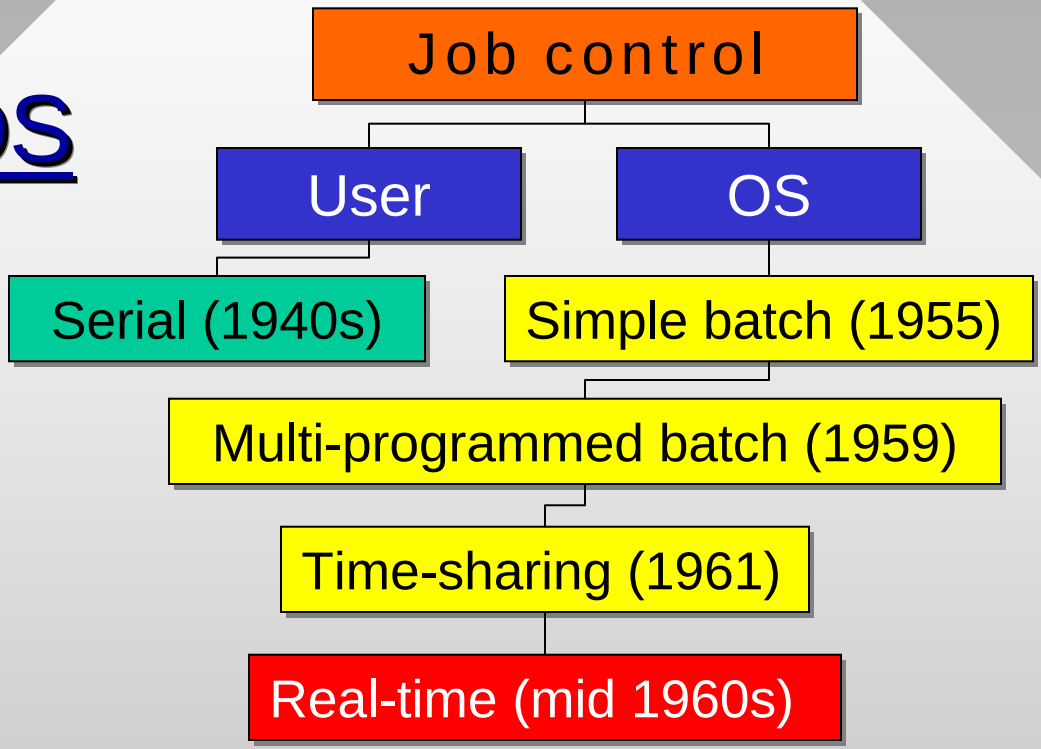
2.6 Traditional UNIX

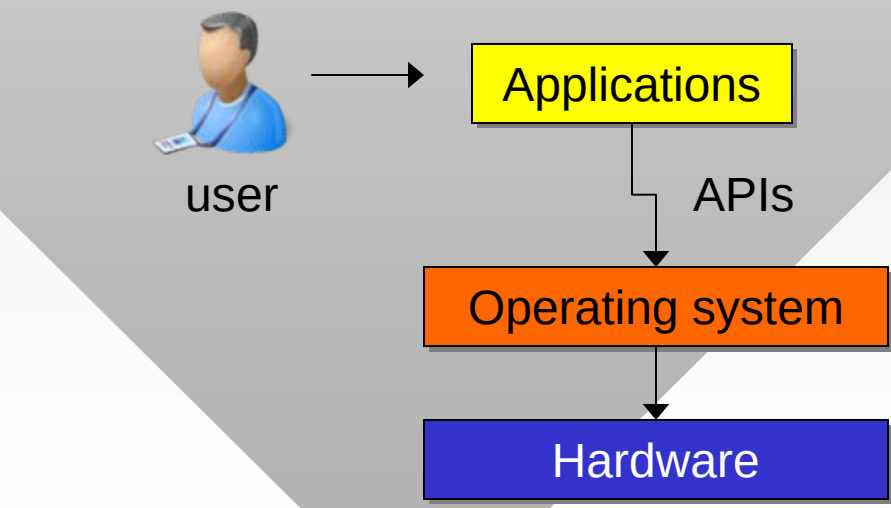
2.7 Modern UNIX

2.8 Linux

# Evolution of the OS

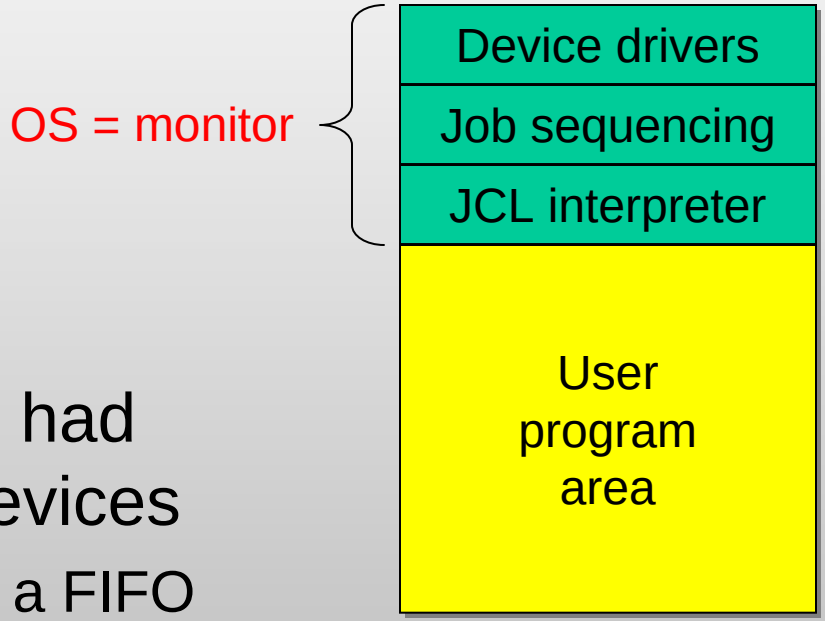
- Manual job control in the 1940s was known as serial processing
- Extreme inefficiency and inconvenience prompted automation of the process and development of an OS
- Main functions
  - Controls the execution of application programs
  - Provides an interface to hardware





# Simple Batch System (1955)

- Early computers were extremely expensive
  - Was important to maximize processor utilization
- After 1955, user no longer had direct access to CPU or devices
  - Instead, submitted jobs into a FIFO queue that was read and executed by a *monitor*
- When programs were done, they returned control to the monitor



- *Job Control Language (JCL)*
  - Directives how to run the job (e.g., compiler, input data, job owner and priority)

# Simple Batch System

Hardware features

- Memory protection
  - Jobs with access violations (e.g., trying to wipe out the monitor) were aborted
- Timer
  - Prevented jobs from monopolizing system or infinitely looping
  - Each job had a fixed deadline by which it had to finish
- Privileged instructions
  - Execution allowed only by the monitor
  - Prevented jobs from crashing the system or reading unauthorized data (e.g., the next job)
  - Monitor controlled all I/O
- Interrupts
  - Were not needed as all I/O was synchronous

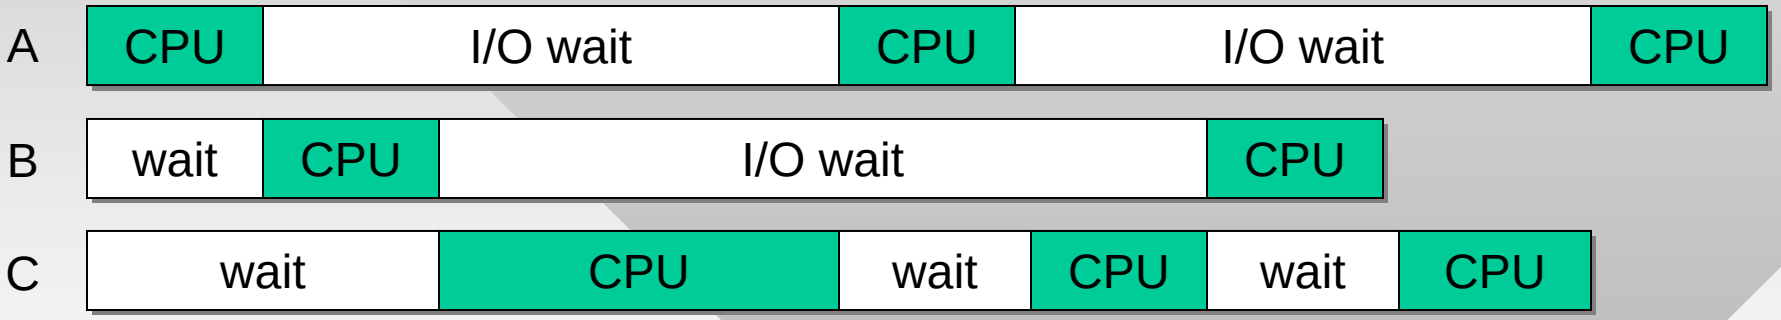
# Multi-Programmed Batch System (1959)

- Even in batched systems, the CPU was often idle
  - Automatic job sequencing helped reduce the delay *between* the jobs, but not *within* them
  - Reason: I/O devices are slow compared to processor
- Example: a job spends 15 ms reading a record from the file, then processes it for 1 ms, and finally writes one record to another file (also 15 ms)
  - What is the CPU utilization?

- This is often called *uni-programming*

# Multi-Programmed Batch System

- Idea: when one job needs to wait for I/O, the monitor can switch the CPU to another job
  - Various scheduling algorithms are possible
  - Example below uses strict priority scheduling from A to C

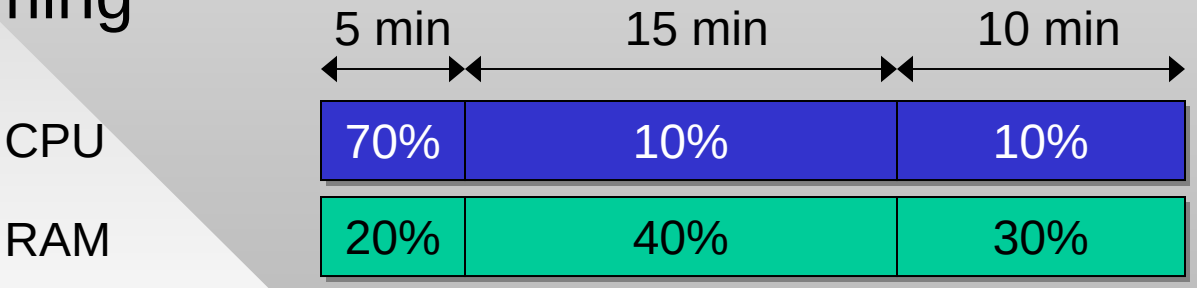


- Interrupts are now needed for monitor to regain control
- This is called multi-programming (or multi-tasking) and is now the central theme of modern OSes

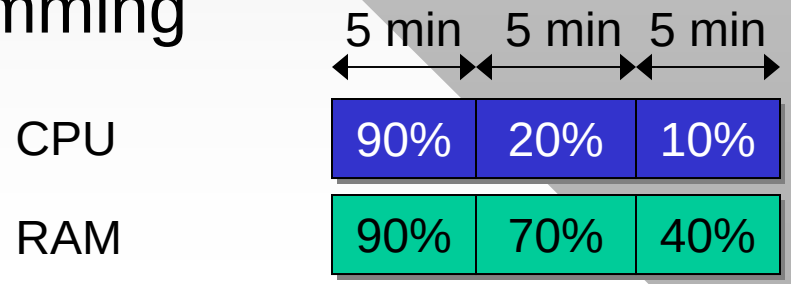
# Example

| | Job 1 | Job 2 | Job 3 |
|---|---|---|---|
| CPU | 70% | 10% | 10% |
| Duration | 5 min | 15 min | 10 min |
| RAM | 50 MB | 100 MB | 75 MB |

- Three jobs are concurrently submitted to a monitor with 250 MB of RAM
  - CPU in table means % of time task is not blocked on I/O
  - Assume jobs never conflict on the same I/O device
- Uni-programming



- Multi-programming



# Example

| | Job 1 | Job 2 | Job 3 |
|---|---|---|---|
| CPU | 70% | 10% | 10% |
| Duration | 5 min | 15 min | 10 min |
| RAM | 50 MB | 100 MB | 75 MB |

- Task 1: completion time of last job in uni-programming?
- Task 2: what is the average CPU and RAM utilization?
  - Metric computed over the entire interval
- Uni-programming

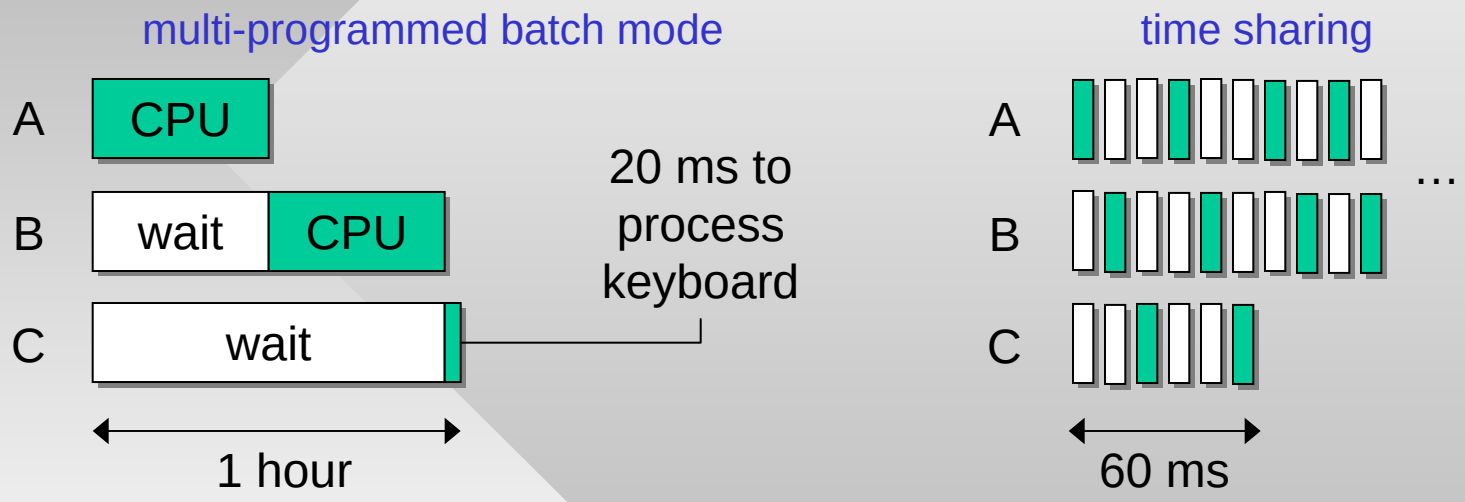
  - CPU: (70%*5 + 10%*15 + 10%*10)/30 = 20%
  - RAM: (20%*5 + 40%*15 + 30%*10)/30 = 33.3%
- Task 3: what is the throughput of the system?
  - Number of jobs finished per time unit (e.g., 1 hour)
- Task 4: what is the mean response time?
  - Average delay from job submission to its completion
  - Uniprocessing: (5 + 20 + 30)/3 = 18.333 min

# Time Sharing System (1961)

- Batch mode favors long CPU-bound jobs
  - Response time for other tasks may be minutes or hours
- Maximizing CPU utilization does not suit interactive jobs
  - E.g., a text editor cannot wait 3 hours for its turn
- Under time-sharing, CPU is periodically provided to all jobs not waiting for I/O
  - Goal: minimize response delay
- Time divided into slices
  - E.g., 200 ms in early systems, 1-10 ms in modern OSes
- The kernel rotates through all jobs scheduling them to run on the CPU
- Max delay before getting on the CPU
  - Slice * (number of competing jobs – 1)

# Time Sharing System

- Comparison



- Response time of C with 10-ms slices?
- First time-sharing OS
  - *Compatible Time-Sharing System* (CTSS), MIT 1961
- Modern OSes derived from these early concepts

# Real-Time System

- In regular OSes, job switching delays are random and depend on the immediate backlog of CPU-bound tasks and their priority
  - Under worst-case scenarios, a job may not receive its turn for many slices
- This presents certain problems in mission-critical applications
  - E.g., car traction control, helicopter missile-guidance system
- Real-time OS (RTOS) provides guarantees on scheduling and interrupt delays
  - Examples include Windows CE, RTLinux, VxWorks

# OS Growth

- OSes are complex pieces of software
  - MIT's CTSS (1961-3): 32,000 machine words
  - IBM's OS/360 (1964): 1M CPU instructions
  - Multics (1978): 20M CPU instructions
- Later, software was measured in source lines of code (SLOC)
  - Estimates from Wikipedia:

| Year | OS | SLOC |
|---|---|---|
| 93 | NT 3.1 | 4M |
| 94 | NT 3.5 | 7M |
| 96 | NT 4.0 | 11M |
| 00 | 2000 | 29M |
| 01 | XP | 45M |
| 03 | Server 2003 | 50M |

| Year | OS | SLOC |
|---|---|---|
| 91 | Linux kernel | 10K |
| 94 | Linux 1.0.0 | 176K |
| 12 | Linux 3.3 kernel | 15M |
| 05 | MacOS 10.4 | 86M |
| 07 | Debian 4.0 | 283M |
| 09 | Debian 5.0 | 324M |

# Chapter 2: Roadmap

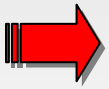
2.1 OS objectives and functions
2.2 Evolution of the OS
2.3 Major achievements
2.4 Other developments
2.5 Virtual Machines
2.6 Multi-core considerations
2.7 MS Windows
2.6 Traditional UNIX
2.7 Modern UNIX
2.8 Linux

# Major Achievements

- Impossible to deal with OS complexity without certain systematic ways of managing resources, jobs, and users
- Major advances in the development of operating systems (layout of the book):
  - Processes and threads (ch. 3-4)
  - IPC (inter-process communication) and synchronization mechanisms (ch. 5-6)
  - File systems (ch. 11-12)
  - Memory (RAM) management (ch. 7-8)
  - Scheduling and resource allocation (ch. 9-10)
  - Information protection and security (ch. 14-15)

covered in this class

# Chapter 2: Roadmap

2.1 OS objectives and functions
2.2 Evolution of the OS
2.3 Major achievements
2.4 Other developments
2.5 Virtual Machines
2.6 Multi-core considerations


2.7 MS Windows
2.6 Traditional UNIX
2.7 Modern UNIX
2.8 Linux

# MS Windows

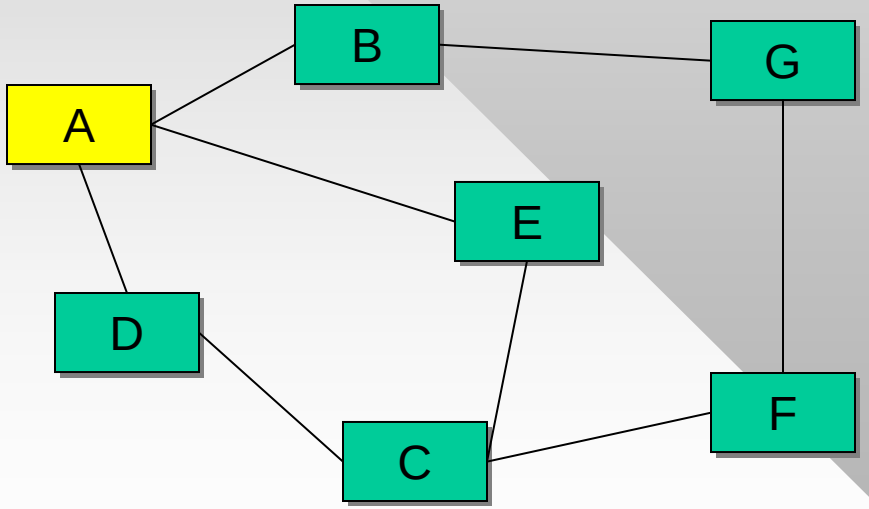
Simple kernel (ntoskrnl.exe)
Hardware abstraction layer (hal.dll)
Hardware

# Homework #1

q = L + (float)w / (d+1)

- When running A*
  - Incorrect # of nodes if weight is integer in q = L + w / (d+1)
- Basic BFS and DFS
  - Order of traversal on this graph?



Adjacency list
A: E, D, B
B: A, G
C: E, D, F
D: A, C
E: A, C
F: C, G
G: B, F

# Homework #1

- Refresh the concept of search
  - Assume an undirected graph G = (V,E)
  - Starting node s$\in$V
- Maintain two structures
  - Unexplored set U
  - Discovered set D
- Approach #1:

```
U.add (s)
while ( U.notEmpty () )
    x = U.removeNextNode ()        // node to explore
    if ( D.find(x) == true )       // if already explored, ignore
        continue
    N = G.getNeighbors (x)         // N is a set of nodes
    if ( N.size() == 0 ) break     // exit?
    for each y in N
        U.add (y)
```

Any problems?

# Homework #1

- This code fails to actually insert anything into D
- Correct version:

```
U.add (s)
while ( U.notEmpty () )
    x = U.removeNextNode ()
    if ( D.find(x) == true )      // if already explored, ignore
        continue
    D.add (x)
    N = G.getNeighbors (x)
    if ( N.size() == 0 ) break    // exit?
    for each y in N
            U.add (y)
```

Any drawbacks?

- Requires huge storage as each node may be pushed into U as many times as there are links to it
  - Not advisable in practice

# Homework #1

- Approach #2 inserts a single copy of each node in U:

```
U.add (s); D.add (s);                  // s = source node
while ( U.notEmpty () )
    x = U.removeNextNode ()
    N = G.getNeighbors (x)
    if ( N.size() == 0 ) break         // exit?
    for each y in N
        if ( D.find (y) == false ) // has been pushed in U?
            U.add (y)
            D.add (y)
```

Always use this version!

- For most types of non-trivial exploration, approach #2 is far superior to #1
- What if D has a function that combines find/add?
  - Can directly use STL set's insert() function
  - Compare the set size before and after the insertion

# Homework #1

- When you find the exit, how far is it from s?
- Idea: make U keep track of tuples (nodeID, distance)

```
U.add (s, 0); D.add (s);
while ( U.notEmpty () )
    t = U.removeNextTuple ()      // t is a tuple
    N = G.getNeighbors (t.ID)
    if ( N.size() == 0 )
         printf ("Found at distance %d\n", t.distance)
         break
    for each y in N
        if ( D.find (y) == false )         // new node?
             U.add (y, t.distance + 1)
             D.add (y)
```

- Note that push() also needs light intensity
  - See the handout for details

# Homework #1

- Reusing the search algorithm
  - Create a base class

```
class Ubase {
          virtual void push (uint64 ID, float intensity) = 0;
          virtual UnexploredRoom pop (void) = 0;
          ...
}
```

  - Inherit four classes

```
class Ubreadth : public Ubase {
          // implement a queue here
}
class Udepth : public Ubase {
          // implement a stack here
}
...
```

```
Ubase *ptr;
if (searchType == BFS)
    ptr = new Ubreadth;
else if ...

Search (ptr);
```

  - Create base pointer to a specific class, then send it to search()

```
Search (Ubase *U)
{
    while (U->size() > 0)
          ...
}
```
