May 16, 2017

## Agenda

- Introduction
- Background
- Unifying framework
- Main results
- Evaluation

## Introduction

- Triangle listing: given a simple undirected graph $G=(V, E)$, identify all 3-node cycles $\Delta_{x y z}$
- Numerous applications
- Network analysis: clustering coefficient, transitivity
- Web/social networks: spam/community detection
- Bioinformatics, graphics, databases, theory of computing
- Many open problems
- Impact of degree distribution on CPU cost, deciding which neighbor traversal order is best, finding the optimal acyclic orientation for a given method, comparing different strategies under their optimal node permutations
- We study these issues in random graphs

## Agenda

- Introduction
- Background
- Unifying framework
- Main results
- Evaluation

## Background

- Triangle listing visits each node and verifies edge existence between each pair of neighbors
- A star graph with 40M nodes requires at least 800T checks
- This is the CPU cost we are interested in studying
- Acyclic orientation: choose a direction along each edge such that the resulting graph has no cycles
- Triangle listing now involves checks among only out-neighbors, only in-neighbors, or some combination thereof
- Orienting edges towards the center and using only out-neighbors reduces verification cost to zero!

## Background

- Given a graph with $n$ nodes, each acyclic orientation can be viewed as some permutation $\theta_{n}$
- Shuffle the nodes and assign sequential labels $1, \ldots, n$
- Direct edges from larger labels to smaller
- List only triangles $\Delta_{x y z}$ such that $x<y<z$
- Suppose the node with a new ID $i$ has out-degree $X_{i}\left(\theta_{n}\right)$, in-degree $Y_{i}\left(\theta_{n}\right)$, and total degree $d_{i}\left(\theta_{n}\right)$
- Then, the CPU cost of all known methods $\mathcal{M}$ is can be expressed by one formula

$$
c_{n}\left(\mathcal{M}, \theta_{n}\right)=\frac{1}{n} \sum_{i=1}^{n} f\left(X_{i}\left(\theta_{n}\right), d_{i}\left(\theta_{n}\right)\right)
$$

- where $f$ is some non-linear function that depends on $\mathcal{M}$

## Background

- Assuming $m$ edges, prior work has shown there exist neighbor search orders where $c_{n}\left(\mathcal{M}, \theta_{n}\right)$ is $O\left(m^{1.5} / n\right)$
- This bound is loose in sparse graphs and has seen no improvement in $\sim 40$ years
- Still unclear how to select the best permutation and neighbor traversal pattern so as to minimize the runtime
- Main obstacle: for a given graph $G$, finding $\theta_{n}$ that optimizes cost is likely an NP-hard problem
- Instead, we seek insight from random graphs
- Suppose $F_{n}(x)$ is a CDF on integers that represents the degree distribution of the graph
- Assume $F_{n}(x) \rightarrow F(x)$ as $n \rightarrow \infty$
- Concerned with expected cost over all graph realizations

## Background

- Berry 2015 obtained the limiting cost for a method we call $\mathrm{T}_{1}$ under descending-degree permutation $\theta_{D}$

$$
\lim _{n \rightarrow \infty} E\left[c_{n}\left(T_{1}, \theta_{D}\right) \mid \mathbf{D}_{n}\right]=\frac{E\left[\left(Z_{1}^{2}-Z_{1}\right) Z_{2} Z_{3} 1_{\left.\min \left(Z_{2}, Z_{3}\right)>Z_{1}\right]}^{2 E^{2}[D]}\right.}{\text { l }}
$$

- where $D_{n}$ is the random degree sequence and $Z_{1}, Z_{2}$, $Z_{3}, D$ are iid with distribution $F(x)$
- Given Pareto degree with $F(x)=1-(1+x / \beta)^{\alpha}$, the limit is finite iff $\alpha>4 / 3$
- Open issues: which permutations/methods are fundamentally better for a given $F(x)$, under what conditions, and does $\theta_{n}$ and neighbor search order change the asymptotics or just constants inside $O($.$) ?$

## Agenda

- Introduction
- Background
- Unifying framework
- Main results
- Evaluation

## Unifying Framework

- We consider three families of algorithms and propose a generalized framework subsumes all previous efforts
- Vertex Iterator (VI): methods $\mathrm{T}_{1}-\mathrm{T}_{6}$ that check neighbor pairs against a hash table
- Scanning Edge Iterator (SEI): methods $E_{1}-\mathrm{E}_{6}$ that run intersection of neighbor lists using sequential scans
- Lookup Edge Iterator (LEI): methods $L_{1}-L_{6}$ that offers no CPU-cost benefits over VI, but have higher I/O
- It may seem that the order in which neighbors are visited (along in/out edges) is unimportant
- However, this makes a noticeable difference!
- Furthermore, improvement in cost is not limited to just constants, but asymptotics as well

## Unifying Framework

- A total of 18 distinct methods, but many have identical cost; need to prune the result

## Unifying Framework

- Four competing algorithms
edge iterator
- To minimize the runtime, need to consider the ratio of cost to speed

| Family of algorithms | Operations | Speed |
| :--- | :--- | ---: |
| Vertex iterator | Hash table | 19 |
| Lookup edge iterator (LEI) | Hash table | 19 |
| Scanning edge iterator (SEI) | SIMD intersection | 1,801 |

Table 3: Single-core speed (million nodes/sec) using an Intel i7-3930K @ 4.4 GHz .

- The speed can be easily benchmarked, what remains is to decide the optimal cost for each method
- Note that $E_{1} / E_{2}$ have strictly more operations that $T_{1} / T_{2}$

## Agenda

- Introduction
- Background
- Unifying framework
- Main results
- Evaluation

## Main Results

| $\mathrm{T}_{1}$ | $\mathrm{~T}_{2}$ | $\mathrm{E}_{1}$ | $\mathrm{E}_{4}$ |
| :---: | :---: | :---: | :---: |
| $\frac{x^{2}}{2}$ | $x(1-x)$ | $\frac{x(2-x)}{2}$ | $\frac{x^{2}+(1-x)^{2}}{2}$ |

- Many assumptions and details omitted (see the paper)
- Theorem: the cost of all 18 methods can be summarized by a sum of functions of order statistics

$$
E\left[c_{n}\left(\mathcal{M}, \theta_{n}\right) \mid \mathbf{D}_{n}\right] \approx \frac{1}{n} \sum_{i=1}^{n} g\left(d_{i}\left(\theta_{n}\right)\right) h\left(q_{i}\left(\theta_{n}\right)\right)
$$

- where $g(x)=x^{2}-x, h(x)$ is given by the table above, and $q_{i}\left(\theta_{n}\right)$ depends only on the permuted degree sequence
- Since the degree $d_{i}\left(\theta_{n}\right)$ is sorted (e.g., $d_{1}\left(\theta_{D}\right)$ is the largest), this sum has some peculiar properties
- Asymptotic behavior of averages in the above form is studied in a field of $L$-estimators

## Main Results

- We leverage Glivenko-Cantelli results for functions of order statistics [Wellner 1978, van Zwet 1980]
- Theorem:

$$
\begin{aligned}
& \lim _{n \rightarrow \infty} E\left[c_{n}\left(\mathcal{M}, \theta_{A}\right) \mid \mathbf{D}_{n}\right]=E[g(D) h(J(D))] \\
& \lim _{n \rightarrow \infty} E\left[c_{n}\left(\mathcal{M}, \theta_{D}\right) \mid \mathbf{D}_{n}\right]=E[g(D) h(1-J(D))]
\end{aligned}
$$

- where $J(x)$ is the spread distribution of $F(x)$
- In particular, $\lim _{n \rightarrow \infty} E\left[c_{n}\left(T_{1}, \theta_{D}\right) \mid \mathbf{D}_{n}\right]=\frac{E\left[g(D)(1-J(D))^{2}\right]}{2}$

$$
\lim _{n \rightarrow \infty} E\left[c_{n}\left(E_{1}, \theta_{D}\right) \mid \mathbf{D}_{n}\right]=\frac{E\left[g(D)\left(1-J^{2}(D)\right)\right]}{2}
$$

## Main Results

- However, non-monotonic permutations require a different approach and new theory
- Suppose $\theta_{n}$ converges to a random map $\xi(u)$
- Random variable $\xi(u)$ specifies the new (permuted) location of nodes $i$ that originate in the vicinity of $u=i / n$
- Theorem: the limiting cost under any convergent sequence of permutations is given by

$$
\lim _{n \rightarrow \infty} E\left[c_{n}\left(\mathcal{M}, \theta_{n}\right) \mid \mathbf{D}_{n}\right]=E[g(D) h(\xi(J(D)))]
$$

- Both the model and derivations are much simpler than in prior work, even though we can handle a much wider class of methods/permutations

## Main Results

- This allows us to establish optimal permutations for certain families of functions $h(x)$
- Theorem: $\mathrm{T}_{1}$ and $\mathrm{E}_{1}$ are both optimized by $\theta_{D}, \mathrm{~T}_{2}$ by round-robin $\theta_{R R}$, and $\mathrm{E}_{4}$ by complementary $\mathrm{RR} \theta_{C R R}$
- $R R$ is a new permutation that places large degree towards the outside of the range $[1, n]$
- CRR is another new permutation that does the opposite (large degree in the center)
- We can finally compare these methods under their respectively optimal $\theta_{n}$
- Theorem: $c_{n}\left(T_{1}, \theta_{D}\right)<c_{n}\left(T_{2}, \theta_{R R}\right)$ for all $F(x)$
- Theorem: $c_{n}\left(E_{1}, \theta_{D}\right)<c_{n}\left(E_{4}, \theta_{C R R}\right)$ for all $F(x)$

## Main Results

- When is VI better than SEI?
- Cost of $\mathrm{T}_{1}$ is finite iff $\alpha>4 / 3$; that of $\mathrm{E}_{1}$ iff $\alpha>1.5$
- Consequently, there are graphs where $T_{1}$ is always faster in the limit no matter what hardware is used
- In real-world graphs, $\mathrm{E}_{1}$ has $2-3 x$ more cost, but 100x faster execution using SIMD intersection (see our ICDM 2016 paper)
- Derived limits are exact for all cases
- Numerically accurate for small $n$ in graphs with constrained degree; for large $n$, whenever the asymptotic cost is finite
- Open issue: accurate models for small $n$, infinite limiting cost, and unconstrained degree
- In summary, both permutation and neighbor visit order change the asymptotics of cost!

## Agenda

- Introduction
- Background
- Unifying framework
- Main results
- Evaluation

## Evaluation: Constrained Graphs

| $n$ | $\mathrm{T}_{1}+\theta_{A}$ |  |  | $\mathrm{T}_{1}+\theta_{p}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | sim | (50) | error | sim | (50) | error |
| $10^{4}$ | 159.1 | 155.6 | -2.2\% | 40.2 | 39.3 | -2.2\% |
| $10^{5}$ | 518.0 | 516.6 | -0.3\% | 87.8 | 87.0 | -0.9\% |
| $10^{6}$ | 1,355.6 | 1,354.5 | -0.1\% | 143.7 | 142.9 | -0.6\% |
| $10^{7}$ | 3,089.1 | 3,089.2 | 0.003\% | 196.9 | 196.2 | -0.4\% |
| $\infty$ | $\infty$ |  |  | 356.3 |  |  |

Table 6: Cost with $\alpha=1.5$ and root truncation.

| $n$ | $\mathrm{~T}_{2}+\theta_{D}$ |  |  | $\mathrm{~T}_{2}+\theta_{R R}$ |  |  |
| :---: | :---: | :---: | ---: | ---: | ---: | ---: |
|  | $\operatorname{sim}$ | $(50)$ | error | $\operatorname{sim}$ | $(50)$ | error |
| $10^{4}$ | 102.3 | 103.7 | $1.4 \%$ | 79.5 | 75.8 | $-4.6 \%$ |
| $10^{5}$ | 260.0 | 261.4 | $0.5 \%$ | 186.4 | 181.8 | $-2.5 \%$ |
| $10^{6}$ | 467.0 | 467.4 | $0.1 \%$ | 315.4 | 310.4 | $-1.6 \%$ |
| $10^{7}$ | 674.6 | 675.4 | $0.1 \%$ | 436.1 | 432.4 | $-0.8 \%$ |
| $\infty$ | $1,307.6$ |  |  | 770.4 |  |  |

Table 7: Cost with $\alpha=1.7$ and root truncation.

## Evaluation: Unconstrained Graphs

| $n$ | $\mathrm{T}_{1}+\theta_{A}$ |  |  | $\mathrm{T}_{1}+\theta_{D}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | sim | (50) | error | sim | (50) | error |
| $10^{4}$ | 7,158 | 6,452 | -9.9\% | 209.5 | 241.1 | 15.1\% |
| $10^{5}$ | 25,770 | 24,303 | -5.7\% | 261.0 | 302.1 | 15.8\% |
| $10^{6}$ | 84,441 | 82,815 | -1.9\% | 294.1 | 333.0 | 13.3\% |
| $10^{7}$ | 274,876 | 270,125 | -1.7\% | 317.0 | 346.9 | 9.4\% |
| $\infty$ | $\infty$ |  |  | 356.3 |  |  |

Table 9: Cost with $\alpha=1.5$ and linear truncation.

| $n$ | $\mathrm{~T}_{2}+\theta_{D}$ |  |  | $\mathrm{~T}_{2}+\theta_{R B}$ |  |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | :---: | :---: |
|  | $\operatorname{sim}$ | $(50)$ | error | $\operatorname{sim}$ | $(50)$ | error |  |
| $10^{4}$ | 499.4 | 854.4 | $71.1 \%$ | 354.5 | 532.6 | $50.3 \%$ |  |
| $10^{5}$ | 725.4 | $1,096.6$ | $51.2 \%$ | 476.5 | 662.3 | $39.0 \%$ |  |
| $10^{6}$ | 907.7 | $1,216.7$ | $34.0 \%$ | 570.2 | 724.4 | $27.0 \%$ |  |
| $10^{7}$ | $1,041.5$ | $1,270.0$ | $21.9 \%$ | 631.2 | 751.5 | $19.1 \%$ |  |
| $\infty$ | $1,307.6$ |  |  |  | 770.4 |  |  |

Table 10: Cost with $\alpha=1.7$ and linear truncation.

## Evaluation: Real Graphs

- Model predictions
- Descending degree is optimal for $T_{1}, E_{1}$
- RR is optimal for $T_{2}$, CRR for $E_{4}$
- The best cost of $E_{1}$ is double that of $T_{2}$
- Degenerate permutation minimizes the largest out-degree

|  | Permutation |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\theta_{D}$ | $\theta_{A}$ | $\theta_{R R}$ | $\theta_{C R R}$ | $\theta_{U}$ | $\theta_{\text {degen }}$ |
| $\mathrm{T}_{1}$ | 150 B | 123 T | 63 T | 31 T | 45 T | 136 B |
| $\mathrm{~T}_{2}$ | 360 B | 360 B | 255 B | 62 T | 41 T | 815 B |
| $\mathrm{E}_{1}$ | 511 B | 123 T | 63 T | 93 T | 86 T | 951 B |
| $\mathrm{E}_{4}$ | 123 T | 123 T | 123 T | 62 T | 82 T | 123 T |

- This improves $\mathrm{T}_{1}$

Table 12: CPU operations on Twitter. by $\sim 10 \%$, but increases cost of the other methods $2-3 x$

## Thank you!
